\textbf{Abstract}

This paper investigates the influence of magnetohydrodynamics oscillatory flow for Carreau fluid through regularly channel with varying temperature for two types of geometries "Poiseuille flow and Couette flow". The fluid is assumed to be non-Newtonian, namely Carreau fluid. The governing equations are solved analytically by the perturbation method. The study is intended to calculate the solution for the small number of Weissenberg number ($We << 1$) to get clear forms for velocity field by assisting the (MATHEMATICA-11) program to obtain the numerical results and illustrations. The physical features of Darcy number, Reynolds number, Peclet number, magnetic parameter, Grashof number and radiation parameter are discussed simultaneously through presenting graphical discussion. The velocity and temperature fields are discussed with different values of involved parameter with the help of graphs.

MSC2010: 76A05, 76Wxx.

1. Introduction

The studies of laminar flow of non-Newtonian fluid have received much attention because it has many applications in science and engineering technology. Fluids differ in their viscosity, which may depend on deformation rate and some fluids have elastic character in nature, which is known as non-Newtonian fluids. Existing literatures indicate that many researchers investigated heat and mass transfer characteristics of non-Newtonian fluids (Nigam and Singh, 1960) [1], (Kavita and others, 2012)[8]. Flow through a porous medium, under the influence of temperature variations, is one of the most important contemporary topics because it finds great applications in geophysics and technology. The study of the flow of sedimentary liquids is of
practical importance, especially flow through packed beds, sedimentation, environmental pollution, and central filtering of particles. (Frigaard and Ryan, 2004)[7] studied the flow of blood through the veins and arteries. Recently, the requirements of modern technology have stimulated interest in fluid flow studies, involving the interaction of many phenomena (Hamza and others, 2011)[5].

(Raptis and others, 1982) [3] studied the effect of heat transfer on magnetohydrodynamics oscillatory flow of Jeffrey fluid in a channel, and have investigated when variable viscosity. (Al-Khatib and Wilson, 2001) [6] have study the heat transfer to magneto hydro dynamics oscillatory flow during a porous medium in slip form.

(Khudair and Al-Khafajy, 2018) [9] have investigated the flow for Williamson fluid for two kinds of geometries "Couette flow and Poiseuille flow" in an inclined channel. influence of heat transfer on magnetohydrodynamics for the oscillatory flow of Williamson fluid with model for two kinds of geometries "Poiseuille flow and Couette flow" through a porous medium channel.

Have made an analytical examination on magnetohydrodynamics boundary layer slip flow in a porous medium over a stretching surface with temperature (Attia and Kotb, 1996) [2]. (Mostafa, 2009) [4] have discussed the effect of chemical reaction effects on magnetohydrodynamics free convection flow in an irregular channel with porous medium.

The study considers a mathematical model for the influence of magneto hydrodynamics oscillatory flow for Carreau fluid through regularly channel with varying temperature.

2. Mathematical Formulation

Consider the flow of a Carreau fluid in the channel of breadth l qualify the effects of magnetic field and Radioactive heat transfer as described in (Fig.1). We supposed that the fluid have very small electromagnetic force produced and the electrical conductivity is small. Cartesian coordinates system such that, (v(y), 0,0) is the velocity vector in which v is the x-component of velocity and y is orthogonal to x-axis.

\[ S = -\overline{p}I + \tau \]  
\[ \overline{\tau} = [\mu_\infty + (\mu_0 - \mu_\infty)((1 + \Gamma^2\gamma)^2)^{n-1}]A^* \]  
\[ \overline{\gamma} = \frac{1}{\sqrt{2}} \sum_j \gamma_{ij} \gamma_{ji} = \frac{1}{\sqrt{2}} \Pi \] and \[ \Pi = tr(A^*)^2, A^* = \Delta \overline{\gamma} + (\Delta \overline{\gamma})^T \]  
\[ \overline{\tau} = \mu_0[1 + (n-1)\gamma^2\gamma^2]A^* \]  
\[ \rho \frac{\partial \overline{\gamma}}{\partial t} = -\frac{\partial \overline{p}}{\partial x} + \frac{\partial \overline{T}x}{\partial x} + \frac{\partial \overline{T}y}{\partial y} + \frac{\partial \overline{T}z}{\partial z} + \rho g \beta (T - T_0) - \sigma B_0^2 \overline{\gamma} - \frac{\mu_0}{k} \overline{\gamma} \]  

Figure.1 Graph of the problem

The fundamental equation for Carreau fluid is (Nadeem,2014) [10] :
\[ \frac{\partial T}{\partial t} = \frac{K}{C_p \partial \psi^2} \frac{1}{C_p} \frac{\partial q}{\partial y} \]  

(6)

The temperatures at the walls of the channel are given as:

\[ T = T_0 \text{ at } \bar{y} = 0, \text{ and } T = T_1 \text{ at } \bar{y} = l. \]  

(7)

In which \( \bar{v} \) is the axial velocity, \( T \) is a fluid temperature, \( B_0 \) is a magnetic field strength, \( \rho \) is a fluid density, \( \sigma \) is a conductivity of the fluid, \( \beta \) is a coefficient of volume amplification due to temperature, \( g \) is an hastening due to gravity, \( k \) is a permeability, \( C_p \) is a specific heat at constant pressure, \( K \) is a thermal conductivity and \( q \) is a radioactive heat flux.

Following (Vinvent and others, 1968) [11], it is supposed that the fluid is visually thin with a relatively low density and the radioactive heat flux is given by:

\[ \frac{\partial \theta}{\partial y} = 4b^2(T_0 - T) \]  

(8)

(\( \theta \)) is a radiation absorption coefficient.

Non-dimensional parameters are (Khudair and Al-Khafaji, 2018) [9]:

\[ v = \frac{\bar{v}}{V}, x = \frac{x}{l}, y = \frac{y}{l}, \theta = \frac{T - T_0}{T_1 - T_0}, t = \frac{tV}{l}, \rho = \frac{\rho h}{\mu V}, M^2 = \frac{\sigma b^2 h^2}{\mu}, Da = \frac{k}{\mu l^2}, Gr = \frac{\rho g b^2 (T_1 - T_0)}{\mu V} \]  

(9)

Where \( V \) is the mean flow velocity, Darcy number \( (Da) \), Reynolds number \( (Re) \), Peclet number \( (Pe) \), magnetic parameter \( (M) \), Grashof number \( (Gr) \) and radiation parameter \( (N) \).

Substituting equations (8) and (9) into equations (5) - (7), we obtain :

\[ \rho \frac{\partial \theta}{\partial t} = -\frac{\mu \nu \partial \theta}{l \partial x} + \frac{-\mu \nu \partial \theta}{l \partial y} + \frac{-\mu \nu \partial \tau}{l \partial x} + \frac{\mu \nu \partial \tau}{l \partial y} + \rho g \beta (T_1 - T_0) \theta - \sigma B_0^2 V \nu - \frac{\mu \nu}{k} V \]  

(10)

\[ \rho \frac{\partial \theta(T_1 - T_0)}{l \partial \tau} = \frac{k}{C_p} \left[ \frac{\partial^2 \theta(T_1 - T_0)}{l \partial \psi^2} - \frac{1}{k} 4b^2(T_0 - T) \right] \]  

(11)

where \( \tau_{xx} = 0 , \tau_{xy} = \mu_0 \left[ \left( 1 + \left( \frac{n-1}{2} \right) (We^2 \gamma^2) \right) \frac{\partial \nu}{\partial y} \right] , \tau_{xz} = 0 \).

The following are the non-dimensional boundary conditions corresponding to the temperature equation:

\[ \theta(0) = 0 , \theta(1) = 1 \]  

(12)

Finally, we get the following non-dimensional equations:

\[ Re \frac{\partial \theta}{\partial \tau} = -\frac{\partial \theta}{\partial x} + \frac{\partial^2 \theta}{\partial y^2} + Gr \theta - \left( M^2 + \frac{1}{Pe} \right) V \]  

(13)

\[ \rho \frac{\partial \theta}{\partial \psi} = \frac{\partial^2 \theta}{\partial \psi^2} + N^2 \theta \]  

(14)

To solve the temperature equation (14) with boundary conditions (12), let

\[ \theta(y, t) = \theta_f(y) e^{i\omega t} \]  

(15)

where \( \omega \) is the frequency of the oscillation.

Substituting the equation (15) into the equation (14), we have

\[ \frac{\partial^2 \theta_f}{\partial y^2} + (N^2 - i\omega Pe) \theta_f = 0 \]  

(16)
The solution of equation (16) with boundary conditions (12) is \( \theta_f(y) = \csc(\varphi) \sin(\varphi) \), where \( \varphi = \sqrt{N^2 - i\omega Pe} \). Therefore

\[
\theta(y, t) = \csc(\varphi) \sin(\varphi)e^{i\omega t}
\]  

(17)

The calculated of equation (13) have been solution in the next parts for two kinds of boundary conditions "Poiseuille flow and Couette flow".

### III. SOLUTION OF THE PROBLEM

#### (i) Poiseuille flow

In this status we suppose that the rigid flakes at \( y = 0 \) and \( y = l \) are at rest. Therefore

\[
\bar{v} = 0 \text{ at } \bar{y} = 0 \text{, and } \bar{v} = 0 \text{ at } \bar{y} = l.
\]

The non-dimensional boundary conditions are:

\[
v(0) = 0, \quad v(1) = 0.
\]  

(18)

To solve the momentum equation (13), let

\[
\frac{-d\rho}{\partial x} = \lambda e^{i\omega t}
\]  

(19)

\[
v(y, t) = v_f(y)e^{i\omega t}
\]  

(20)

where \( \lambda \) is a real constant.

Substituting the equations (19) and (20) into the equation (13), we have:

\[
Re \frac{\partial}{\partial t}(v_f(y)e^{i\omega t}) = \lambda e^{i\omega t} + \frac{\partial}{\partial y} \left( (1 + \frac{n-1}{2})(We)^2 \left( \frac{\partial}{\partial y} (v_f(y)e^{i\omega t}) \right)^2, \frac{\partial}{\partial y} (v_f(y)e^{i\omega t}) \right) (v_f(y)e^{i\omega t}) + Gr\theta_f -
\]

\[
\left( M^2 + \frac{1}{Da} \right) (v_f(y)e^{i\omega t})
\]  

(21)

Equation (21) is non-linear and it is difficult to get an exact solution. So for waning (We), the boundary value problem is agreeing to an easy analytical solution. In this case the equation can be solved. Nevertheless, we suggest a small \( \Gamma \) and used the perturbation technique to solve the problem. Accordingly, we write:

\[
v_f = v_{00} + We^2v_{02} + O(We^4)
\]  

(22)

Substituting equation (22) in equation (21) with boundary conditions (18), then we equality the powers of (We), we obtain:

**A - Zeros-order system (We^0)**

\[
\frac{\partial v_{00}}{\partial y^2} - \left( M^2 + Rei\omega + \frac{1}{Da} \right) v_{00} = -(\lambda + Gr\theta_f)
\]  

(23)

The associated boundary conditions are:

\[
v_{00}(0) = v_{00}(1) = 0
\]  

(24)

**B - Second-order system (We^2)**

\[
\frac{\partial v_{01}}{\partial y^2} - \left( M^2 + Rei\omega + \frac{1}{Da} \right) v_{01} = -3(n-1)2 \left( \frac{\partial v_{00}}{\partial y} \right)^2 \left( \frac{\partial^2 v_{00}}{\partial y^2} \right) e^{i\omega t}
\]  

(25)

The associated boundary conditions are:

\[
v_{01}(0) = v_{01}(1) = 0
\]  

(26)
Finally, the perturbation solutions up to second order for $v_f$ is given by

$$v_f = v_{00} + W e^2 v_{02} + O(We^4)$$

Therefore, the fluid velocity is given as:

$$v(y, t) = v_f(y)e^{i\omega t}$$  \hspace{1cm} (31)

(ii) **Couette flow**

The upper flake is locomotion and the lower flake is fixed with the velocity $V_h$. The boundary conditions for the Couette flow problem defined as:

$$v(0) = 0, \quad v(1) = V_0$$  \hspace{1cm} (32)

We have same defined as the governing equation in Poiseuille flow equation (21). The solution in this case has been calculated by the perturbation technique and the results have been discussed during graphs.

**IV. RESULTS AND DISCUSSION**

We are discussed influence of magnetohydrodynamics oscillatory flow for Carreau fluid through regularly channel with varying temperature for Poiseuille flow and Couette flow in some results during the graphical illustrations. Numerical assessments of analytical results and some of the graphically significant results are presented in Figure (2-14).

We used the MATHEMATICA program to find the numerical results and illustrations. The momentum equation is resolved by using "perturbation technique" and all the results are discussed graphically.

The velocity profile of Poiseuille flow is shown during Figure (2-6). Figure.2 illustrates the influence $Da$ and $M$ on the velocity profiles function $v$ vs. $y$. It is found by the increasing $Da$ the velocity profiles function $v$ increases, while $v$ decreases with increasing $M$. Figure.3 show that velocity profile $v$ rising up by the increasing influence of both the parameters $Gr$ and $\lambda$. Figure.4 we observed that $v$ increases by the increasing influence of both the parameters $Re$ and $Pe$. Figure.5 show the velocity profile $v$ increases by the increasing $N$, and show that by the increasing $\omega$ the velocity profile $v$ decreases.

The fluid velocity starts to be constant at the walls and increasing, as fixed by the boundary conditions. Figure.6 show that velocity profiles increases with the increasing of the parameters $We$ when $0.45 < y < 1$, while $v$ decreases by the increasing of $We$ when $0 < y < 0.45$. The velocity profile of Couette flow is shown during Figure (7-11). It is noted that by the increasing Each of parameters $Re, Pe, Gr, Da, N$ and $\lambda$ the velocity profile $v$ increases, while $v$ decreases by the increasing $We, M$ and $\omega$.

Based on Eq. (17), figure.12 show that influence of $N$ on the temperature function $\theta$. The temperature increases by the increase in $N$. Figure.13 we observed that the influence $Pe$ in temperature $\theta$ by the increasing $Pe$ then $\theta$ increases. Figure.14 show as that by the increasing of $\omega$ the temperature $\theta$ decreases.

V. CONCLUSION AND REMARKS

We discuss the influence of magnetohydrodynamics oscillatory flow for Carreau fluid through regularly channel with varying temperature. We found the velocity and temperature are analytically.

We used different values to finding the results of pertinent parameters namely for the velocity and temperature ($Re$, $Pe$, $N, Da, Gr, \lambda, M, \omega, We$). The key point are:

- The velocity profiles increases by the increasing $Pe, N, Da, Gr$ and $\lambda$ for both the Poiseuille and Couette flow.
- The velocity profiles decreases by the increasing $\omega$ and $M$ for both the Poiseuille and Couette flow.
- The velocity profiles increases by the increasing of the parameters $We$ when $0.45 < y < 1$, while $\nu$ decreases with increasing of $We$ when $0 < y < 0.45$, for Poiseuille flow. The velocity profiles decreases with the increasing of the parameters $We$ for Couette flow.
- We show that by the increases $N$ and $Pe$ the temperature increasing $\theta$ and the temperature $\theta$ decreases by the increasing $\omega$.
